ABSTRACT

Introduction: Traditional medicines for mammary tumour are unreasonable and have genuine symptoms. Non-ordinary normal medications have increased wide acknowledgment because of their assurance of a cure with negligible or no symptoms, however minimal experimental confirmation exists. One such basic cure is the leaves of the Euphorbia hirta plant.

Methods: It is initially reported utilization of the fluid concentrate of Euphorbia hirta leaves breast cancer cells. The capacity of the concentrate to impel apoptosis and corruption in the human bosom malignancy cell line MCF-7, contrasted with typical human skin fibroblasts (MDA MB-231), was dictated by morphological changes in the cells utilizing light microscopy, DNA fragmentation, and brilliant stains (Annexin V and Propidium Iodide) utilizing Flow Cytometry and fluorescent microscopy. Results: Apoptosis was instigated in both cells, and more in MCF-7, when they were treated with 25% and half concentrate, while rot was watched mostly after presentation to raised concentrate fixations (75%). DNA discontinuity came about for both cells, in a period and dosage subordinate way. Both cells, at all concentrate fixations, demonstrated no critical contrasts in the quantity of living, dead, apoptotic, and necrotic cells. Conclusion: At long last, the outcomes might show that apoptotic changes in MCF-7 might be free of caspase-3, which is included in apoptosis and is inadequate in MCF-7 cells.

Key words: Apoptosis, Aqueous extract, Euphorbia hirta leaves, Human breast cancer cells, Necrosis.

INTRODUCTION

Cancer is a major cause of death worldwide with breast cancer being the most common cancer and a leading cause of death in females in many parts of the world. Both conventional and non-conventional treatments of cancer are widely used. Non-conventional treatments are attractive due to their claim to counteract the problems of conventional treatments, such as high cost and serious side effects.

Many natural dietary agents, including vegetables, fruits, herbs, and spices have been used in traditional medicines, as non-conventional treatments, for thousands of years, but without sufficient scientific proofs. If effective, natural agents might lead to the development of natural and novel drugs with low or no side effects.

Numerous epidemiological, biological and clinical studies indicate a strong correlation between dietary factors and lower risk for developing cancer. Dietary factors can prevent cancers, and they, on the other hand, can induce cancers.

Many dietary agents, such as curcumin (in turmeric) and epigallocatechin-gallate (in green tea), have been shown to cause induction of apoptosis and cell cycle arrest in many types of cancer cells without affecting normal cells. Cruciferae or Brassicaceae vegetables, such as garden cress (LepidiumEhirta, [Euphorbia hirta]), and their active ingredients have been found to stimulate apoptosis in cancer cells, thereby killing cancer cells specifically without harming normal healthy cells.

The leaves of the Euphorbia hirta plant, which are used in folk remedies, have many activities including thermogenic, depurative, rubefacient, tonic, aphrodisiac, abortive, ophthalmic, diuretic, and contraceptive. They are useful as poultices for sprains and in leprosy, ophthalmopathy, leucorrhoea, scurvy, seminal weakness, bronchial asthma, cough, and hemorrhoids. Euphorbia hirta leaves are recommended in the treatment of various ailments, but in therapeutic doses because of their known toxicity if used in high doses, although there is no scientific evidence.

The healing effects of natural dietary agents are partially due to the constituent phytochemicals. Many studies demonstrate and describe the various therapeutic effects of plant phytochemicals, which include the prevention and/or prevention of cancer. The most important phytochemicals (phenolic compounds, terpenoids, alkaloids, and organosulfur compounds) are all found in Euphorbia hirta leaves. Euphorbia hirta also contains plant phytosterols and their derivatives, which have been shown to possess antioxidant potential, anti-inflammatory activity, and to protect against some illnesses and cancers. Phenolic compounds, most importantly the flavonoids, may protect the human body from oxidative stress that may lead to cancer, aging, and cardiovascular diseases.

The chemopreventive and anti-cancer effects of Cruciferous vegetables have also been attributed to the presence of high levels of organosulfur compounds, which have been shown to exert diverse biological effects, including induction of carcinogen detoxification, inhibition of tumor cell proliferation, free radical scavenging, induction of cell cycle arrest, and induction of apoptosis. The oil of the Euphorbia hirta leaves is rich in alpha linolenic acid, and contains an ideal ratio of ω-3 fatty acids (n-3) and ω-6 fatty acids (n-6). Recent studies proved the preventive effect of ω-3 polyunsaturated fatty acids, especially alpha linolenic acid, on different types of cancer, including breast, in both animals or cell line models, and in the treatment of cancer.

Glucosinolates, a class of thioglycosides, are major secondary metabolites of Euphorbia hirta leaves and leaves and have been shown to inhibit carcinogenesis and have chemopreventive effects against the development and proliferation of cancers.

As presented above, some researchers have shown that certain constituents of the Euphorbia hirta plant and the alcoholic extracts of its different parts have chemopreventive and anti-cancer effects, but, to our
knowledge, no studies exist on the effects of the aqueous extract of *Euphorbia hirta* leaves on the viability and growth of cancer cells. Therefore, the potential of *Euphorbia hirta* to induce death of human breast cancer cells in tissue culture is investigated here in the hope of finding a natural treatment.

**MATERIALS AND METHODS**

**Cell lines**
The human breast cancer cell line MCF-7 (Michigan Cancer Foundation-7) (ATCC, Pune), is an epithelial invasive breast ductal carcinoma cell line, which is estrogen and progesterone receptor positive. Both MCF-7 and MDA MB 231 were cultured in Dulbecco’s minimal essential medium (DMEM) supplemented with 10% fetal bovine serum (FBS) (both GIBCO, Grand Island, NY, USA), 1% L-glutamine, 1% penicillin, and streptomycin and incubated in 5% CO₂ atmosphere, at 37°C, and 96% relative humidity.

**Preparation of the Aqueous Extract**
*Euphorbia hirta* leaves were obtained locally and they were powdered using an electric grinder. The extract was prepared by dissolving 1 g of *Euphorbia hirta* leaves powder in 99.87 ml of deionized water and adding 0.14 ml of DMSO, thereby leading to a 0.1% DMSO for the highest used concentration of extract (75%). Several dilutions of the extract in serum-free medium (SF M) were prepared [extract: SFM (vol/vol); 1:3 (25% of extract), 1:1 (50%), and 3:1 (75%)], and were stored at −80°C.

**Determination of Cells’ Morphology Using Light Microscopy**
To determine the effects of *Euphorbia hirta* leaves extract on the morphology of the cells, both MCF-7 and MDA MB 231 cells were suspended in DMEM containing 10% FBS and then leaved on a cover slip placed in a Petri dish. After 24 h, the original DMEM was replaced with 5 ml of SFM containing one of the different concentrations of *Euphorbia hirta* leaves extract (25%, 50%, or 75%), while the control contained only 0.1% DMSO in SFM. After 48 h, the medium was discarded, and the cells were then stained with Coomassie blue. Finally, the cells were observed and photographed on an Eclipse E400 light microscope attached to a Nikon F-601 camera.

**DNA Extraction, Purification And Electrophoresis**
Both MCF-7 and MDA MB 231 cells (1.5×10⁵ cell/ml) were suspended in DMEM containing 10% FBS, and subsequently cultivated on 6-well plates at 5 ml/well. After 24 h, the original DMEM was replaced with 5 ml of SFM containing a concentration (25%, 50%, or 75%) of *Euphorbia hirta* leaves extract. The control used was as described above. The cells were treated in a time-or dose-dependent manner. One group of both cells was exposed to 25%, 50%, or 75% extract and incubated for 72 h, while another group of both cells was treated only with 50% of extract and incubated for 24, 48, or 72 h.

The cells were harvested by adding 1 ml/well of trypsin to separate adherent cells and then 3 ml/well of SFM to stop the effect of trypsin and harvest the cells. The cells were subsequently centrifuged at 1500 rpm for 10 min. Each pellet was washed with PBS and then centrifuged, as above, and the process was repeated. The resultant pellets were stored at −20°C until the time of DNA extraction.

DNA from both types of cells was extracted and purified using a DNA extraction kit according to the manufacturer’s protocol. The resultant purified DNA was stored at −20°C until DNA electrophoresis.

Isolated DNA samples were subjected to electrophoresis on a 1.5% agarose gel for 45 min at 100 volt. The gel was visualized under UV light following ethidium bromide staining to determine DNA fragmentation.

**Quantitative Determination of Apoptosis And Necrosis Using Flow Cytometry**
The two major types of cell death, necrosis and apoptosis, produced by the effects of the extract on MCF-7 and MDA MB 231 cells were detected by the CF488A-Annexin V and Propidium Iodide kit by using flow cytometry and fluorescent microscopy (below). MCF-7 and MDA MB 231 cells (2×10⁵ cell/ml) were cultivated in DMEM containing 10% FBS, at 10 ml per Petri dish. Upon formation of a monolayer of cells, 10 ml of a concentration (25%, 50%, or 75%) of *Euphorbia hirta* leaves extract were added. As above, the control was SFM containing 0.1% DMSO. After 24 h of incubation, cells were harvested by the addition of trypsin, centrifuged for 5 min at 1000x, and finally washed with PBS. Cells were stained according to the kit’s protocol, and were analyzed by a BD FACSC an to ІІ Flow Cytometer, at the National Guards Hospital, Jeddah, KSA. The determinations were performed in duplicates.

**Statistical Analysis**
Statistical comparisons of the percentages of living and dead cells were performed using the three-way ANOVA test followed by the Dunnett’s multiple comparisons test. For the differences in the results, the P-value was used to determine statistical significance. A difference with a *P*-value <0.05 was considered statistically significant.

**RESULTS**

**The Morphology of the Extract on the Morphology of Cells**
Upon the incubation of cells with increasing concentrations of extract, for 48 h, apoptotic cells were more frequently seen. The most common apoptotic morphological changes observed in both cells included chromatin condensation, cytoplasm shrinkage, and loss of normal shape followed by breaking up of the nucleus into discrete fragments by budding of the cell as a whole to produce membrane-bound apoptotic bodies.

Figure 1A: shows that an MCF-7 cell treated with 0.1% DMSO retains its normal angular or polygonal shape. Most cells have intact and large vesicular nuclei with prominent nucleoli. MDA MB 231 cells treated with 0.1% DMSO show (Figure 2A) a normal spindle shape and intact large oval, and vesicular nuclei with two prominent nucleoli. MCF-7 (Figure 1B) and MDA MB 231 (Figure 2B) cells treated with 25% extract show loss of the normal sheet-like growth and most of the remaining few cells had shrunken cytoplasm, condensed chromatin and loss of normal shape.

MCF-7 (Figure 1C) and MDA MB 231 (Figure 2C) cells treated with 50% extract showed a significant loss of cell processes and marked changes in morphology associated with late stage of apoptosis, such as shrinkage, irregular shape, and condensed and fragmented chromatin and cytoplasm, to produce apoptotic bodies. A marked and visible increase in the number of necrotic cells was observed. Necrotic MCF-7 and MDA MB 231 cells (Figures 1 and 2D, respectively) appeared after incubation with...
Figure 1: Effects of *E. hirta* leaves extract on the morphology of MCF-7 cells after 48 h of treatment. The cells were examined under an Eclipse E400 light microscope using a 100× objective lens. (A) Shows an MCF-7 cell treated with 0.1% DMSO only. The cell has normal angular or polygonal shape with intact and large vesicular nucleus and prominent nucleolus (arrow). (B) Represents an MCF-7 cell treated with 25% extract that has lost its normal shape and shows a shrunken cytoplasm and condensed chromatin (arrow). (C) Represents an MCF-7 cell treated with 50% extract that shows evident signs of apoptosis including cytoplasm and chromatin condensation, and fragmentation and formation of apoptotic bodies (lines). (D) Represents an MCF-7 cell treated with 75% extract that shows signs of necrosis. The cell has more or less a normal polygonal shape with a poorly defined nucleus (arrow), clear vesicles in the cytoplasm (line) and disrupted cell membrane with leaking cell contents (dashed arrows).

Figure 2: Effects of *E. hirta* leaves extract on the morphology of MDA MB 231 cells after 48 h of treatment. The cells were examined under Eclipse an E400 light microscope using a 100× objective lens. (A) Represents an MDA MB 231 cell treated with 0.1% DMSO that shows a normal spindle shape and intact large, oval, and vesicular nucleus with two prominent nucleoli (arrows). (B) Represents an MDA MB 231 cell treated with 25% extract that lost its normal shape and shows a shrunken cytoplasm and condensed chromatin (arrow). (C) Represents an MDA MB 231 cell treated with 50% extract with evident signs of apoptosis (cytoplasm and chromatin condensation and fragmentation) and formation of apoptotic bodies (lines). (D) Represents an MDA MB 231 cell treated with 75% extract that shows signs of necrosis, including clear nucleus (arrow), clear vesicles in the cytoplasm (lines), and disrupted cell membrane with leakage of cell contents (dashed arrow).

Figure 3: Electrophoresis of DNA extracted from MCF-7 MDA-MB-231 cells after treatment with extract of different concentration and incubation time. Lane 1-: DNA from the cells of control. Lane 2-: DNA treated with 25% extract for 72 h. Lane 3-: DNA treated with 50% extract for 72 h. Lane 4-: DNA treated with 75% extract for 72 h. Aim-: 1 KBP DNA marker. Lane 5-: DNA treated with 50% of extract for 24 h. Lane 6-: DNA treated with 50% of extract for 48 h and Lane 7-: DNA treated with 50% of extract for 72 h.
**Figure 4:** The extract induced apoptosis and necrosis in both MCF-7 and MDA MB-231 cells after 24 h of incubation. The cells were examined under a Nikon Eclipse 50i Nikon microscope using a 20× objective lens. Viable cells do not take any color (Annexin V⁻/PI⁻), early apoptotic cells (Annexin V⁺/PI⁻) are green, late apoptotic cells (Annexin V⁺/PI⁺) are green and orange, and necrotic cells (Annexin V⁻/PI⁺) are orange. (A1–A4) represent MCF-7 cells and (B1–B4) represent MDA MB 231 cells that were treated with extract (control, 25%, 50%, and 75% extract, respectively). (A1–A4 and B1–B4) represent fluorescence images and (A1'–A4' and B1'–B4') correspond to interference contrast images. Continuous arrows indicate early apoptotic cells, dashed arrows indicate late apoptotic cells, and dotted arrows indicate necrotic cells.

**Figure 5:** Fluorescent staining of early and late apoptotic cells and necrotic cells of both MCF-7 and MDA MB 231 cells. (A1 and B1) represent MCF-7 and MDA MB 231 cells, respectively, treated with 0.1% DMSO only (controls). (A2 and B2) represent MCF-7 and MDA MB 231 cells.

75% extract and showed clear cytoplasmic vacuoles, disrupted membrane and leakage of cellular contents.

Chromosomal DNA Fragmentation
DNA fragmentation is a hallmark feature of apoptosis. Both MCF-7 (Figure 3A) and MDA MB 231 (Figure 3B) cells treated with extract in a time- or dose-dependent manner induced a smear pattern of DNA fragmentation with both high molecular weight DNA and smaller DNA fragments compared with the used DNA ladder that extends from 20 kb to 75 bp. The control for each cell type, treated with 0.1% DMSO for 72 h, showed clear bands of intact DNA and the smear pattern of damaged DNA.

Determination of Apoptosis and Necrosis Using Cytometry
Using the three-way ANOVA followed by factorial design, flow cytometry revealed (Table 1) no significant differences between the percentages of living, dead, early and late apoptotic, and necrotic cells for MCF-7 and MDA MB 231 cells treated with 25%, 50%, or 75% extract compared with the respective (untreated) controls. The majority (~90%) of detached cells remained unstained, with intact membrane, and no phosphatidylserine translocation suggesting that they were living cells. Flow cytometry also revealed (Table 2) no significant differences between the percentages of both apoptotic (late and early) and necrotic cells for each extract concentration used for the two cell lines.

Determination of Apoptosis and Necrosis Using Fluorescence Microscopy
Annexin V is a protein that is conjugated to a green fluorescent dye to detect apoptosis. Propidium iodide (PI) is a red fluorescent dye that stains DNA of both necrotic and late apoptotic cells with damaged membranes.

Fluorescence microscopy was used to provide qualitative identification of both apoptotic and necrotic deaths of both MCF-7 and MDA MB 231 cells treated for 24 h with different concentrations (25%, 50% or 75%) of extract (Figure 4). Both MCF-7 and MDA MB 231 cells that were treated with 0.1% DMSO (Figures 4 and 5A1; and Figures 4 and 5B1, respectively) were viable and negative to annexin V and PI. A few of both cell types treated with 25% of extract were positive to annexin V and PI, indicating the presence of early and late apoptotic cells (Figure 4A2 and B2). A high number of both cells treated with 50% of extract (Figure 4A3 and B3; and Figure 5A2 and B2) were positive to annexin V and PI, indicating the presence of early and late apoptotic cells with few necrotic cells. The effect of 50% of extract was weaker on MDA MB 231 compared with MCF-7 cells (Figure 4A3 and B3, respectively), but the living MDA MB 231 cells had abnormal morphology. The effect of 75% of extract (Figure 4A4 and B4) was stronger on both cells, with no living cells and only a few dead cells were observed, and most of these cells were early or late apoptotic cells and necrotic cells.

DISCUSSION
When cells become old or damaged, they die by apoptosis, necrosis or a combination of the two and are replaced with new cells. On the other hand, cancer cells are immortal since they are resistant to apoptosis. Chemotherapy kills cancer cells through apoptosis and/or necrosis. The induction of apoptosis and necrosis in MCF-7 and MDA MB 231 cells by the aqueous extract of Euphorbia hirta leaves was monitored by analysis of morphological changes in the cells using light microscopy, DNA fragmentation assay, and fluorescent stains (Annex-V and VI) using flow cytometry and fluorescent microscopy. Results demonstrated the occurrence of both types of cell death in MCF-7 and MDA MB 231 cells following addition of the extract to the culture medium. Apoptosis was induced when cells were treated with 25% and 50% extract, but necrosis was observed mainly after the cells were exposed to elevated concentrations (75%) of extract.
Under light microscopy, the normal angular and spindle shapes of MCF-7 and MDA MB 231 cells, respectively, treated with 0.1% DMSO, were observed, but they were lost after treatment with the extract. The number of dead cells by apoptosis and necrosis increased with increasing concentrations of extract.

Apoptotic cells with their unique morphology, including cell shrinkage, chromatin condensation and finally nuclear and cytoplasm condensation and fragmentation and formation of apoptotic bodies, were observed after 48 h of exposure to the different concentrations of the extract. At 75% concentration, the majority of cells die and cells with apoptotic and necrotic morphology were observed. This is in contrast to the 25% and 50% concentrations, where apoptosis was the main type of cell death observed.

It is interesting to note that MCF-7 cells are one of the breast cancers that are known to be resistant to currently used chemotherapeutics due to deletion in the CASP-3 gene that leads to an inherited deficiency of caspase-3. Caspase-3 is commonly activated by numerous death signals and cleaves a variety of important cellular proteins. It is responsible for DNA fragmentation and some of the distinct morphological features of apoptotic cells such as shrinkage and budding.23

The results of light microscopy to determine cell morphology proved that apoptotic changes were independent of caspase-3, which is lacking in MCF-7 cells. From these results one can suggest that apoptosis induced by Euphorbia hirta leaves extract does not correlate with the activation of caspase-3 but may activate different apoptotic pathways and other effector caspses such as caspase-6 or -7.36

Therefore, there must be other chemical agents in the extract that induce apoptosis and exert the hallmark features of apoptosis independent of the activation of caspase 3. Another researcher48 described typical apoptotic morphological changes in MCF-7 cells treated with the chemical compound pyrrolo-1, 5-benzoxazepine (PBOX-6) in a dose- and time-dependent manner. MCF-7 cells also exhibited apoptotic morphological changes when treated with chloroform extract of Gmelinaasiatica.39 MDA MB 231 exposed to staurosporine for 8 h was described by Johansson et al.49 to show typical signs of apoptosis as demonstrated by using light microscopy and electron microscopy.

A typical DNA ladder pattern was not evident in either MCF-7 or MDA MB 231 cells treated with Euphorbia hirta leaves extract in a time- or dose-dependent manner. This may indicate that the cells die by apoptosis and/or necrosis, where DNA damage is not a unique feature of apoptosis but can also occur in necrosis.37 DNA extracted from apoptotic cells often show a ladder pattern and the presence of a smear pattern may indicate that the apoptotic cells enter into late apoptosis (secondary necrosis) because of the absence of phagocytosis to remove cell remnants.48 Or that some cell lines, such as MCF-7, can undergo apoptosis without showing DNA fragmentation due to lack of caspase-3 which is responsible for this feature.32 Another explanation may be that the long incubation time of DNA led to lyses of a substantial part of the cell population. The smear pattern was also observed in the controls for both cell types that were treated with 0.1% DMSO for 72 h, which confirms the previous explanation. The DNAs isolated from the controls of both cell types exhibited one clear band (for each cell types) that pointed to the presence of living cells with intact DNA strand.

DNA fragmentation was induced24 in four human breast cancer cell lines (MDA-MB-231, MDA-MB-468, MCF-7, and T47D cells) after treatment with sulforaphane, an isothiocyanate found in Cruciferous vegetables, for 96 h. DNA fragmentation was also detected in Jurkat cells exposed to BITC at different concentrations for 20 h, but not detected at a high concentration.39

Detecting apoptosis and/or necrosis by flow cytometry and fluorescent microscopy after staining with fluorescent dyes, both MCF-7 and MDA MB 231 cells treated with different concentrations of Euphorbia hirta leaves extract (25%, 50%, or 75%) for 24 h exhibited both apoptotic and necrotic changes.

Flow cytometry showed that the number of dead MCF-7 cells was not significantly different from that found for MDA MB 231 cells. The apoptotic and necrotic cells were observed in both types of cells treated with different concentrations of Euphorbia hirta leaves extract. There were no significant changes in the percentages of different types of dead cells (early and late apoptosis and necrosis) for both MCF-7 and MDA MB 231 treated with different concentrations of extract, compared with the control cells.

Under fluorescent microscopy, after 24 h of extract exposure, both types of control cells (0.1% DMSO) were viable and did not undergo apoptosis or necrosis. Apoptotic cells decreased and necrotic cells increased with exposure to increasing concentrations of Euphorbia hirta leaves extract. Early and late apoptotic cells were detected at 25% extract concentration, and early and late apoptotic cells and necrotic cells were observed at 50% concentration. MCF-7 cells were more affected by the extract than MDA MB 231 at 25% and 50%. For both cell types, a fewer number of cells were observed after treatment with 75% concentration due to the strong effect of this concentration, and most remaining cells were apoptotic or necrotic cells.

Similar results were reported in a study,40 using flow cytometry, of HT-29 colorectal cells treated with allylisothiocyanate, an isothiocyanate found in Cruciferous vegetables, for 24 h, which showed no signs of apoptosis, where the percentage of both apoptotic and necrotic cells in untreated control cells was significantly higher than the cells treated with allylisothiocyanate. Allylisothiocyanate increased the percentage of apoptotic cells in a concentration-dependent manner (after 24 h) in both prostate PC-3 and LNCaP cells in comparison with control treated with DMSO.41 A significant increase in the percentage of apoptosis was observed in the prostate cancer cells (Capan-2) that were treated for 24 h with BITC in comparison with control. Flow cytometry and fluorescent microscopy of human brain cancer SHG-44 cell line treated with the water extract of Chinese medicne “PingliuKeli” (which is composed of nine plants) for 24 h, after being stained with annexin V and PI, showed both apoptotic and necrotic cells that increased with increasing concentrations of extract.42 Fluorescent microscopy indicated43 that the methanol extract of adencalymma alliaceum flowers induce time-dependent apoptosis in both MCF-7 and MDA MB-231 breast cancer cells treated for 6 and 12 h, with less prominent necrosis.

**CONCLUSION**

Aqueous extract of E. hirta was equally, and even more in some experiments found effective against MCF-7 cells compared to MDA MB 231 cells. In general, the highest (75%) dose of extract was cytotoxic for both MCF-7 and MDA MB 231 cells in most assays.

It is recommended that further work be done using the lowest concentration of the extract on MCF-7 and other types of breast cancers and for longer incubation periods. This might help reduce or eliminate the toxic and damaging effects of the high concentrations of the extract on the healthy cells while, at the same time, possibly getting better effects on the cancer cells due to the extended period of incubation. Another area of further research is to work on the active ingredients of the extract with different types of cancer.
